 November 2000 (2000-11-16).

Novelty and inventive step

1.1 D1 describes an optical DNA sensor chip for detecting hybridizing DNA. DNA targets are marked with fluorophores (corresponding to the ligands).

These targets bind to immobilized DNA probes (corresponding to the receptors) (page 120, left-hand column, abstract). "Molecular beacons" are used as DNA probes in order to increase the sensitivity (page 121, left-hand column, second paragraph). As indicated in the present application (page 4, lines 11-37), these "beacons" have a fluorchrome. The DNA

probes are also biotinylated (page 122, right-hand column, third paragraph and page 121, table). The optical sensor system in D1 enables targets marked with fluorophores to be detected. It appears that the use of "beacons" also containing a fluorophore also makes possible separate detection of receptormarker molecules (in D1, a"molecular beacon" as DNA probe).

- 1.2 D2 describes a DNA biosensor for detecting nucleic acids. This biosensor consists of a "biochip" containing multiple biological sensor elements, namely DNA probes (receptor-marker complex). The DNA probes are immobilized on a detector surface (column 7, second paragraph). Example 15 indicates that the gene "probes" are marked with fluorescein.

 Therefore, in D2 it is also possible for the receptor-marker complexes to be detected independently of the receptor-ligand complexes.
- 1.3 D3 (WO-A-0 068 692) indicates that both the immobilized antigens and the antibodies can be spectrally detected (figure 1C). In D3, receptormarker complexes can be determined independently of the receptor-ligand complexes.

In contrast to these documents, claim 1 of the present application is restricted to methods for determining receptors on a carrier. The receptors cannot be detected until after they are immobilized, since receptor-marker complexes are not formed until after immobilization.

 Each of these documents, independently of each other, is regarded as the closest prior art. With

INTERNATIONAL PRELIMINARY EXAMINATION REPORT

these documents as the point of departure, the problem to be solved by the present application can be regarded as that of improving a method for determining the number of receptors on a carrier surface, wherein the number of receptors actually immobilized can be precisely determined. The solution as presented in claims 1-23 involves methods in which receptor-marker complexes can be detected independently of receptor-ligand complexes.

Although the cited documents do not suggest this method, the application contains no evidence of this actual effect. It contains no tests that suggest this effect. In order for the invention to involve a technical effect, it has to be achievable throughout the entire scope of the claims. This has not been demonstrated, and therefore an inventive step cannot be acknowledged.

Therefore, claims 1-23 are not admissible pursuant to PCT Article 33(3).

3. It is also noted that claim 23 is drafted in the form of a "product-by-process" claim. The PCT Contracting States do not have uniform criteria for assessing the industrial applicability of this type of claim. For the EPO, this type of claim, in which products are characterized by the production method, is admissible only if the products per se satisfy the criteria for patentability, and therefore if the products per se are novel and inventive.
